An approach of ovarian reserve test

Author: Dr. Alberto Martinez Duran
Tutor: Dr. Chardonnens
Objective

To review the literature regarding diminished ovarian reserve, the screening techniques that are currently available or under investigation and the appropriate application in clinical practice.

The ability of a woman to conceive in the absence of specific pathophysiological changes in her reproductive system determined by her reproductive potential. Scott 1995
This capacity declines with age

Physiological reasons. Exponentially declines in the number of follicles. Inhibin ? E2 ? FSH ?
Age

**Fertility rate in women declines with age** Fertility rates in different groups of women from the 16th to the 20th centuries. The fertility rate declined with age in all the groups. (Redrawn from Maroulis, GB, Seminars Reprod Endocrinol 1991; 9:165.)
Age

Age-dependent decline in pregnancy and livebirth rates.

**Table 1** Basal FSH and ovulation in women ≥ 40

Scott et al Fertil Steril Vol 51, No 4 April, 1989
Intercycle variability in basal FSH levels.

• <15 mIU/mL very low variation, mean value 2.6 ± 0.2 mIU/mL.
• Patients with elevated FSH levels, high variation mean value 7.4 ± 0.9 mIU/mL.
Intercycle variability in basal FSH levels.

- In the same study, there are patients with normal or intermediate range during one cycle and elevated in another.
- Maybe these patients needed to be monitored from cycle to cycle and then stimulated in the cycle when the FSH levels were normal.
LH and E2

- Evaluation of basal E2 and LH and pregnancy rates revealed no consistent relationship.
- The individual analysis FSH, LH and E2 levels and pregnancy outcome
E2

**E2 (pg/ml)**

% Pregnant Per Attempt

- Total pregnancies
- Ongoing Pregnancies

E2 (pg/ml)

- <5

- 15-19.9
- 20-24.9
- >=25
The clomiphene citrate test.

• Measuring serum FSH concentrations on cycle day 3 (basal).
• Administration of 100 mg of clomiphene citrate on day 5 to 9.
• Measuring serum FSH concentrations on cycle day 10.
Hypothesis

In women with normal ovarian reserve, the overall increase in estradiol and inhibin production by developing follicles should be able to overcome the impact of clomiphene citrate on the hypothalamic-pituitary axis, and suppress FSH levels into the normal range (10 Day cycle).
Clomiphene citrate test

Predictive value.

- Predictive value of an abnormal test for failing to become pregnant was 100% (Tanbo 1989, Loumayed 1990).
- Predictive value of an abnormal test for cycle cancellation was 85% (Tanbo 1989) and 31.2% (Loumayed 1990).
Scott, 1993.

- The authors studied 236 women from the general infertility population and found:
  - Abnormal clomiphene citrate test 10%.
  - Incidence of abnormal test rose with age.
  - Pregnancy rates in abnormal citrate clomiphene test was 9%.
  - Pregnancy rates in normal citrate clomiphene test was 43%.
  - Only 7 of the 23 patients with abnormal test had elevated day 3 FSH levels.
Clomiphene citrate test.

It is a test that unmasks patients who might not be detected by basal FSH screening alone.
Inhibins

Inhibins are multifunctional molecules (Petraglia 1993):

– Involved in the control of the pituitary gonadotropin secretion, selective control of the secretion of follicle stimulating hormone (FSH) during the menstrual cycle.

– Ovarian follicular development.

– Placental function.

– Spermatogenesis.

– Inhibins are currently recognized as paracrine ovarian regulators and have multiple paracrine effects in the utero-placenta unit.
Sources

• Granulosa and theca cells (ovary).
• Sertoli cells (testis)
• Extragonadal tissues (bone, marrow, brain, pituitary, liver, adrenal).
**Patterns**

Inhibin A: circulating levels are low in the early state of the follicular phase and rise from late follicular phase after a short indentation coinciding with the LH peak.
Patterns of inhibin A

-14 -7 0 7 14

Day of cycle

Inhibin-A level (pg/ml)

younger women older women
Inhibin B: rises sharply from the early follicular phase, with a peak following the FSH rise and progressive fall during the remainder of the follicular phase.

Another peak of it is observed two days after the midcycle peak followed by a rapid decrease during luteal involution.
Patterns of inhibin B

Inhibin-B level (pg/ml)

Day of cycle

younger women  older women
Changes in serum levels of inhibin during menstrual cycle, reproductive aging, pre- and post menopause

![Bar chart showing changes in serum levels of inhibin A and inhibin B during different stages of reproductive life.](chart.png)
Inhibin B

• Predicts ovarian reserve in older infertile women undergoing the citrate clomiphene test (CCT):
  – Abnormal CCT?  Inhibin 3DayB  3dayFSH
    E2 levels normal

• Inhibin B day 3 decreases before a rise in the day 3 FSH.

• Early indicator of ovarian function??

(Petraglia, 1999)
Antral follicle count by transvaginal ultrasonography.

- Decrease in the quality of oocytes.
- Gradual reduction in the number of primordial follicles.

Te Velde 1998
Declining follicle number with age

A comparison of the relationship between age and primordial follicle number in Block’s study of 44 girls and women aged 7 to 44 years with that of Gougeon’s study of women aged 45 to 55 years. Follicle depletion appears to accelerate in the decade preceding menopause. (Data from Block, E, Acta Anat 1952; 14:108 and Gougeon, A, Contraception Fertile Sexual 1984; 12:527.)
Antral follicle count by transvaginal ultrasonography.

- The number of primordial follicles appears to be correlated with the number of growing follicles (Gougeon, 1984).
- The decline in primordial follicle reserve leads to a decrease in size of the antral follicle cohort (Schefer, 1999).
- manifests as a reduction in the number of dominant follicles developing in response to high doses of exogenous gonadotropins (Jacobs, 1990).
Antral follicle count by transvaginal ultrasonography.

Adapted from Chang et al. Fertil Steril Vol 69, No 3, March 1998
Antral follicle count by transvaginal ultrasonography.

• Overall conception rate was higher for those with 4 follicles than for those with < 3 follicles (Chang, 1998).

• There is a relationship between follicle count, age < 40 years, serum day 3 FSH levels of < 10 mlU/mL. (Pache 1990.)
Ovarian volume

- Ovarian volume progressively decreases with age.

- The ovarian volume:
  - Formula prolate ellipse:
    - $0.523 \times \text{length} \times \text{width} \times \text{thickness}$.

Syrop 1995
Discussion

Age related changes in sexual hormones during the intervening years probably because of the decline in oocyte quality and reduced number of follicles followed by a decrease in inhibin concentration and its loss would explain the elevated FSH with age despite the normal plasma E2 concentrations.
Discussion

- In any attempt to study variations in fecundity as a function of a woman’s age two major problems are encountered:

  • the need to separate the influence of the woman’s age from associated variables such as the pattern of coitus and the age of the husband.

  • the variable under study - the age of the woman - can itself result in bias, since time introduces a type of selection\textsuperscript{66}. 
Discussion

• FSH
  – The intercycle variability of basal FSH has been reported.
  – There is a variation in FSH and E2 levels among laboratories despite the use of similar assay techniques.
Discussion

• Clomiphene Citrate test.
  – Abnormal: revealed PRs uniformly poor independent of patient's age.
  – Normal: with increased age, it revealed a significant diminution in pregnancy rates.

• The importance of considering patient’s age even when CCT result are normal.
Discussion

• **Antral follicle count and ovarian volume**
  – Repeated cycle-cycle measurements of antral follicular count and ovarian volume revealed only moderate agreement.
  – A plausible explanation could be that the size of the follicle cohort varies among different cycles.
Conclusion

- Age is a determining factor for fertility.
- Elevated Day 3 FSH levels are highly predictive of diminished ovarian reserve.
  - The test is simple, inexpensive and routinely available.
Conclusion

• An abnormal CCT has excellent predictive value for diminished ovarian reserve.
  – It is quite specific
  – It is 2 to 3 times more sensitive than basal FSH.
  – The literature does not contain enough data to recommend omission of day 3 FSH.
Conclusion

• Transvaginal ultrasound is an easy method to complement other predictive factors of ovarian responsiveness.
Recommendations for screening.

Scott 1995

- All infertile woman over the age of 30 should be screened because ovarian reserve begins to diminish approximately at that time.
- Younger women with unexplained infertility should be screening because an abnormal test may approach 50% of these patients.
