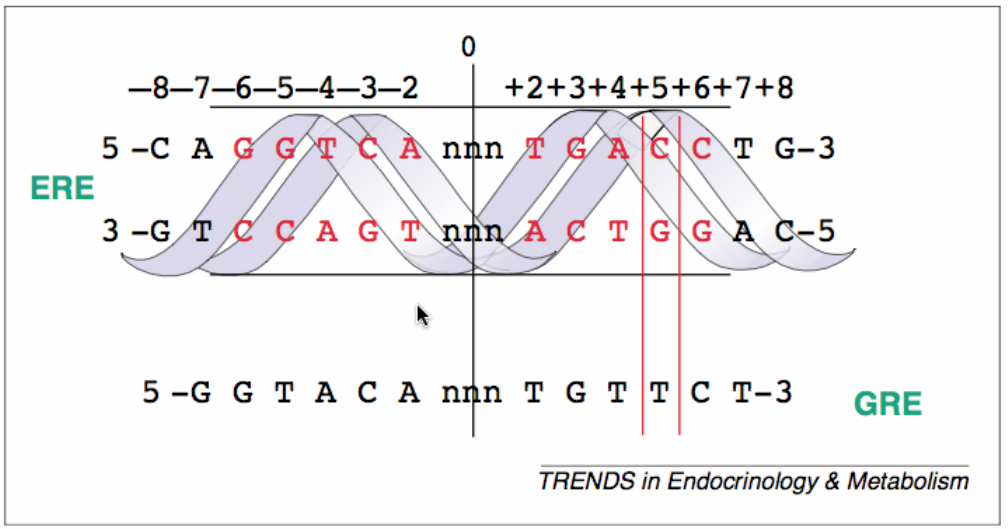

Figure 1. Sequence of the ERE and GRE. **(a)** A consensus ERE has been derived from several highly estrogen-responsive sequences from the African clawed frog *Xenopus laevis* genes encoding vitellogenin A1, A2, B1, B2 and the chicken apo-VLDL II gene. It is a 13 bp perfect palindromic inverted repeat with a 3 bp spacing of variable bases (red). **(b)** The sequence of the consensus GRE [11]. As indicated, replacement of the adenine base at position +4 by thymine results in the generation of a GRE. Positions +2, +3 and +6 are conserved in both the ERE and GRE. Abbreviations: ERE, estrogen response element; GRE, glucocorticoid response element.

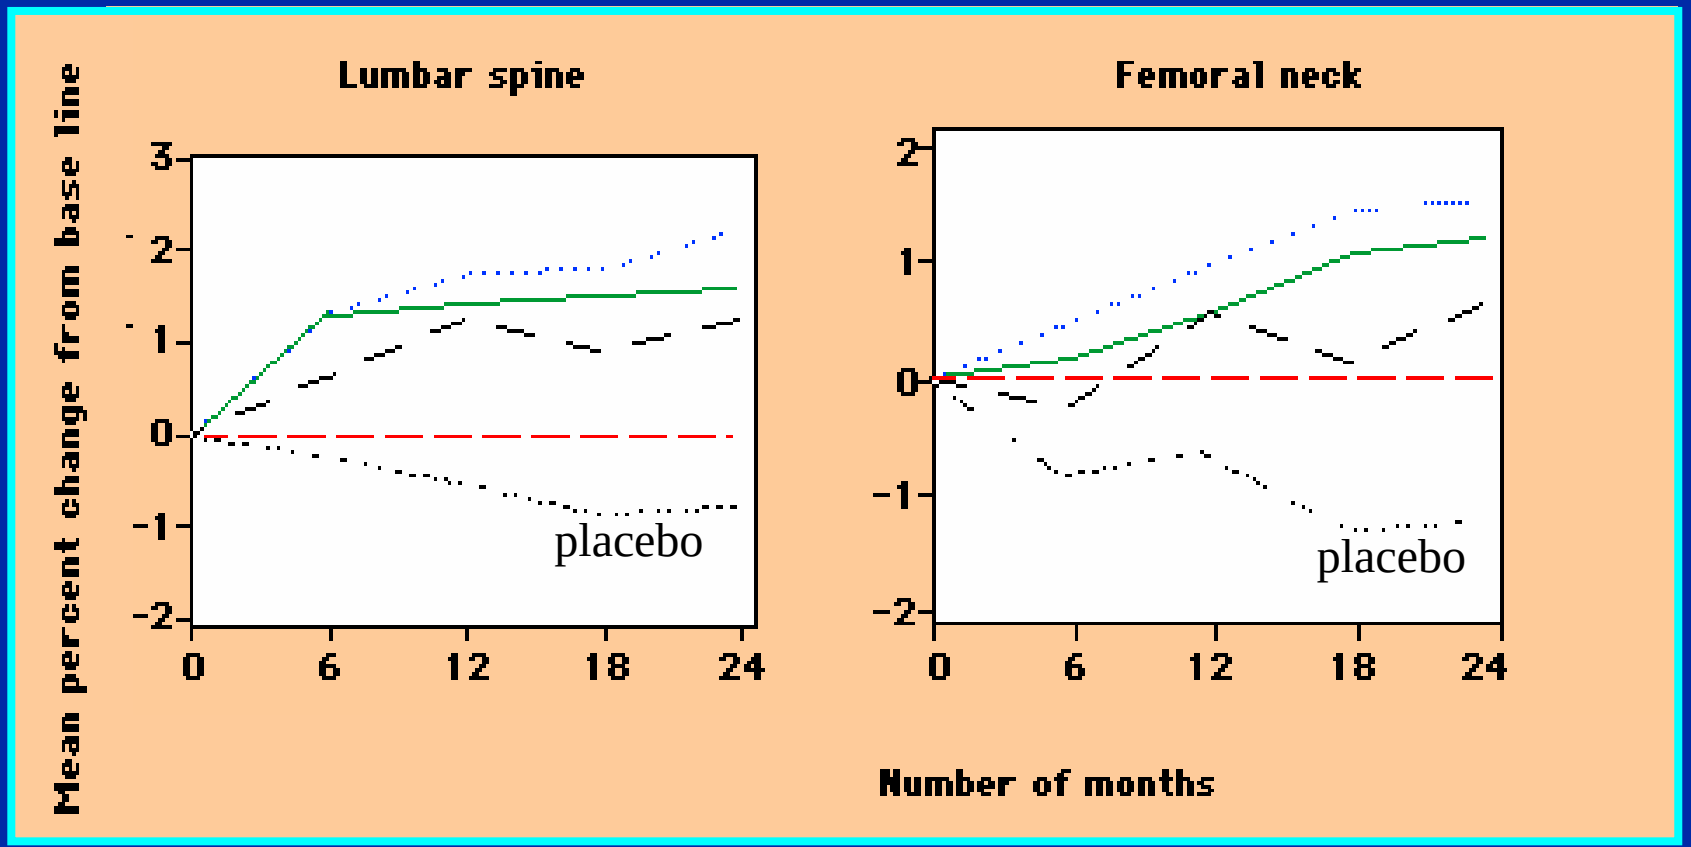
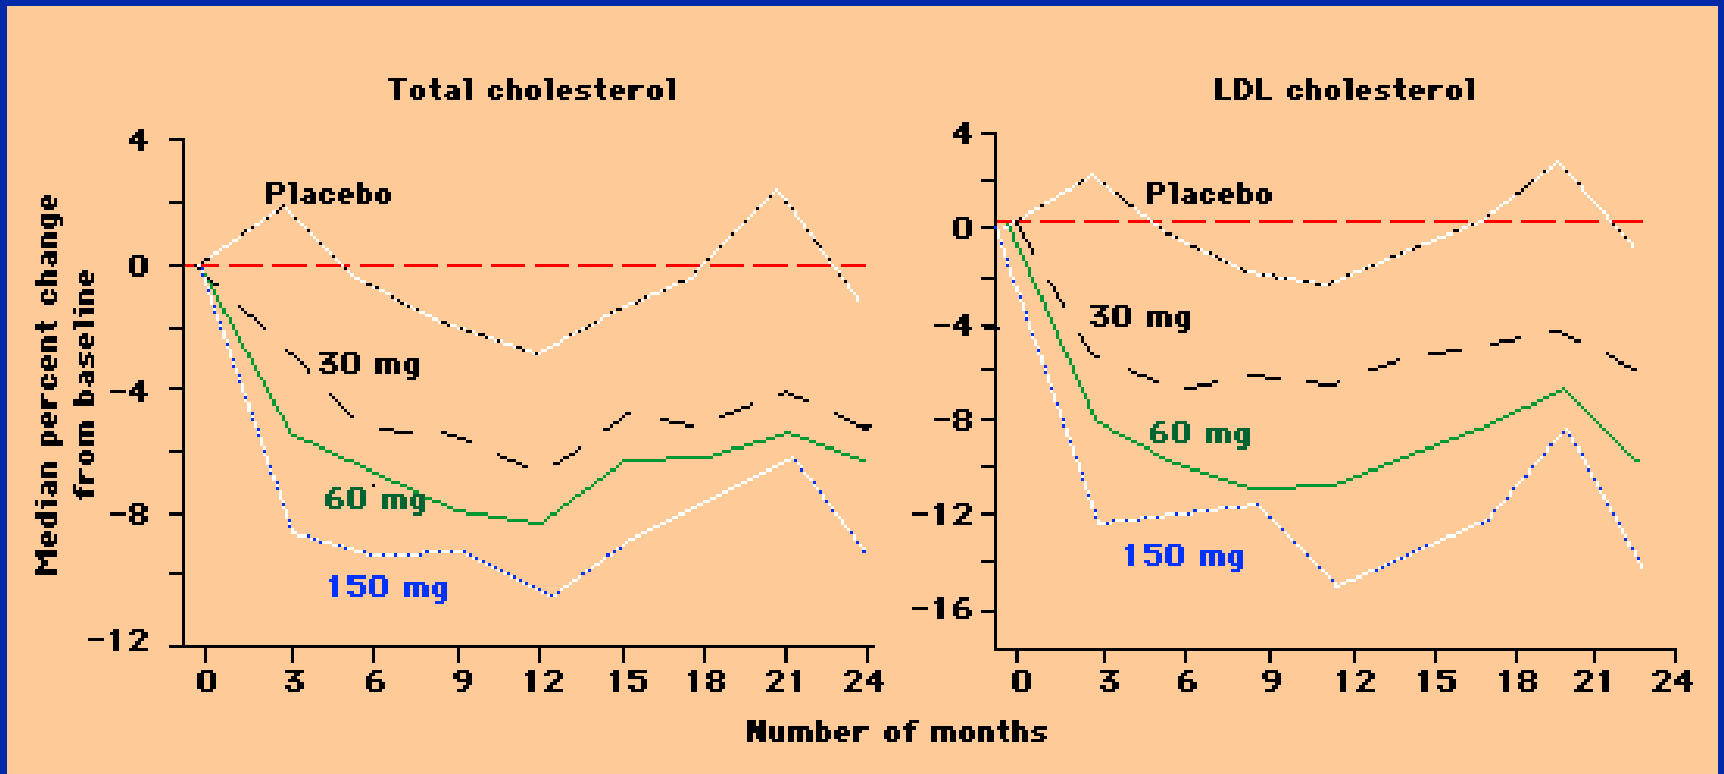
Effects of raloxifene on bone



Bone mineral density increases with raloxifene in postmenopausal women Administration of raloxifene at varying doses (30 mg, black dashed line; 60 mg, green line; 150 mg, blue dotted line) resulted in an increase in bone mineral density compared to placebo (black dotted line) in all sites tested over two years. Redrawn from Delmas, PD, Bjarnason, NH, Mitlak, BH, et al, N Engl J Med 1997;337:1641.

Effects of raloxifene on lipids



Serum total cholesterol and HDL cholesterol concentrations decrease with raloxifene therapy in postmenopausal women Raloxifene administered in three different doses (30 mg, black dashed line; 60 mg, green line; 150 mg, blue dotted line) resulted in significant decreases in serum total and HDL cholesterol compared to placebo (black dotted line) over the two year follow-up. Redrawn from Delmas, PD, Bjarnason, NH, Mitlak, BH, et al, N Engl J Med 1997;337:1641.

Raloxifene and Cardiovascular Events in Osteoporotic Postmenopausal Women

Four-Year Results From the MORE (Multiple Outcomes of Raloxifene Evaluation) Randomized Trial

Context Raloxifene, a selective estrogen receptor modulator, improves cardiovascular risk factors, but its effect on cardiovascular events is unknown.

Objective To determine the effect of raloxifene on cardiovascular events in osteoporotic postmenopausal women.

Design Secondary analysis of data from the Multiple Outcomes of Raloxifene Evaluation trial, a randomized, double-blind, placebo-controlled trial conducted between November 1994 and September 1999.

Setting Outpatient and community settings at 180 sites in 25 countries.

Participants A total of 7705 osteoporotic postmenopausal women (mean age, 67 years).

Intervention Patients were randomly assigned to receive raloxifene, 60 mg/d (n=2557), or 120 mg/d (n=2572), or placebo (n=2576) for 4 years.

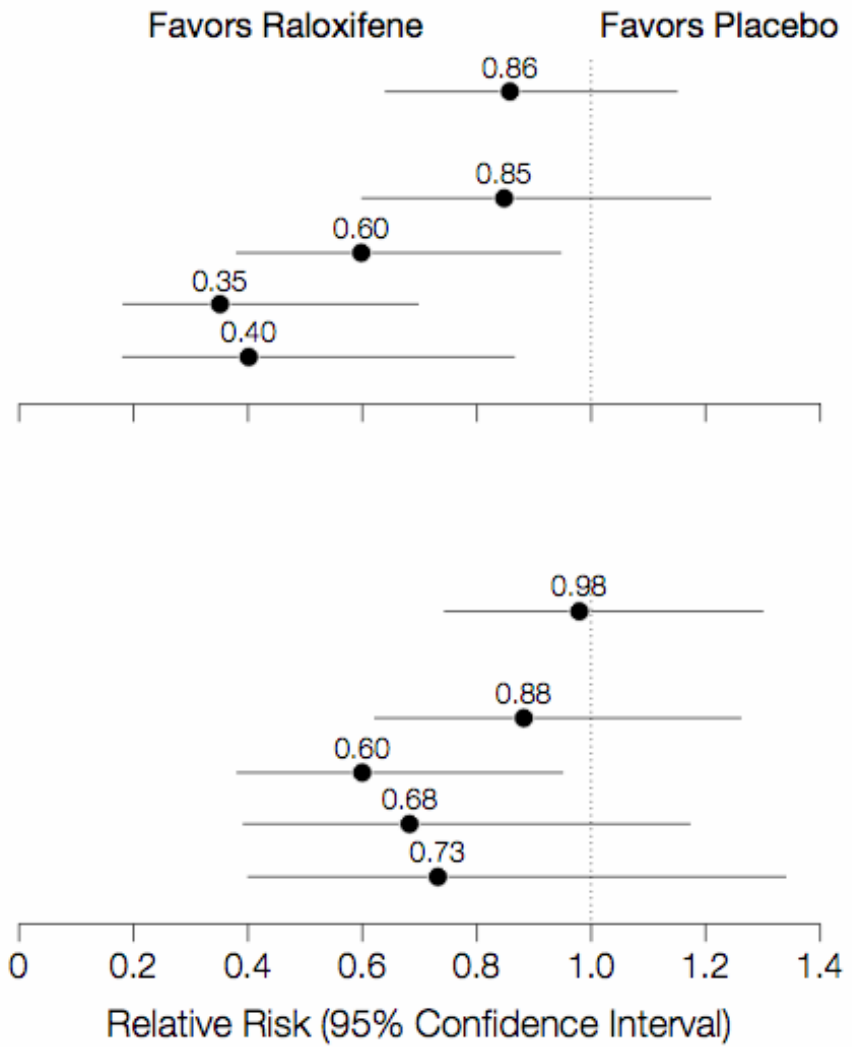
Figure 4. Relative Risk of Any Cardiovascular Events Compared by Raloxifene and Placebo

A Raloxifene 60 mg/d

	No. of Women	No. of Events
Overall	5133	178
Cardiovascular Risk Score		
≥3	1726	118
≥4	676	69
≥5	252	32
≥6	186	26

B Raloxifene 120 mg/d

	No. of Women	No. of Events
Overall	5148	190
Cardiovascular Risk Score		
≥3	1665	116
≥4	676	69
≥5	272	43
≥6	209	35



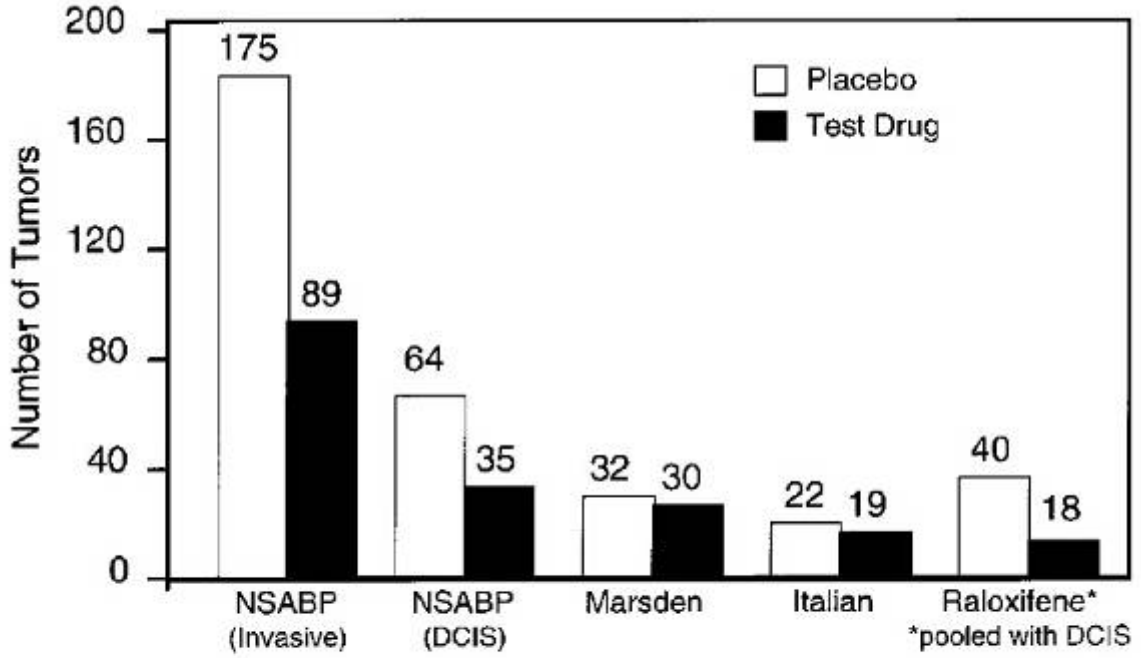


FIG. 13. A comparison of the able-to-be-evaluated events observed in the studies to reduce the incidence of breast cancer. The NSABP P-1 trial is the only prospective clinical trial designed to test the worth of an antiestrogen to prevent breast cancer in 13,388 high-risk women. The figure illustrates the effect of tamoxifen on both invasive and noninvasive (ductal carcinoma *in situ* DCIS) breast cancer. By contrast, the Royal Marsden Study is a pilot project (209) originally designed to be a toxicity evaluation (211) in 2,471 high-risk women, and the Italian study reports (210) at least one year's data from an original population of 5,408 young women of normal risk. Finally, the raloxifene data that can only be estimated from published abstracts (240, 241), constitute a secondary end point from 10,553 postmenopausal women in osteoporosis trials. The reported cases are both invasive and noninvasive breast cancers.

Table 3. Tissue-Selective Estrogenic Effects of Raloxifene

Tissue	Agonistic Effects	Antagonistic Effects	Uncertain
Skeleton	Yes		
Lipids	Yes		
Hemostasis	Yes		
Breast		Yes	
Uterus		Yes	
Vasomotor		Yes	
Ovary			Yes
Pituitary gland and brain			Yes

Another type of SERMs: Endocrine disrupters

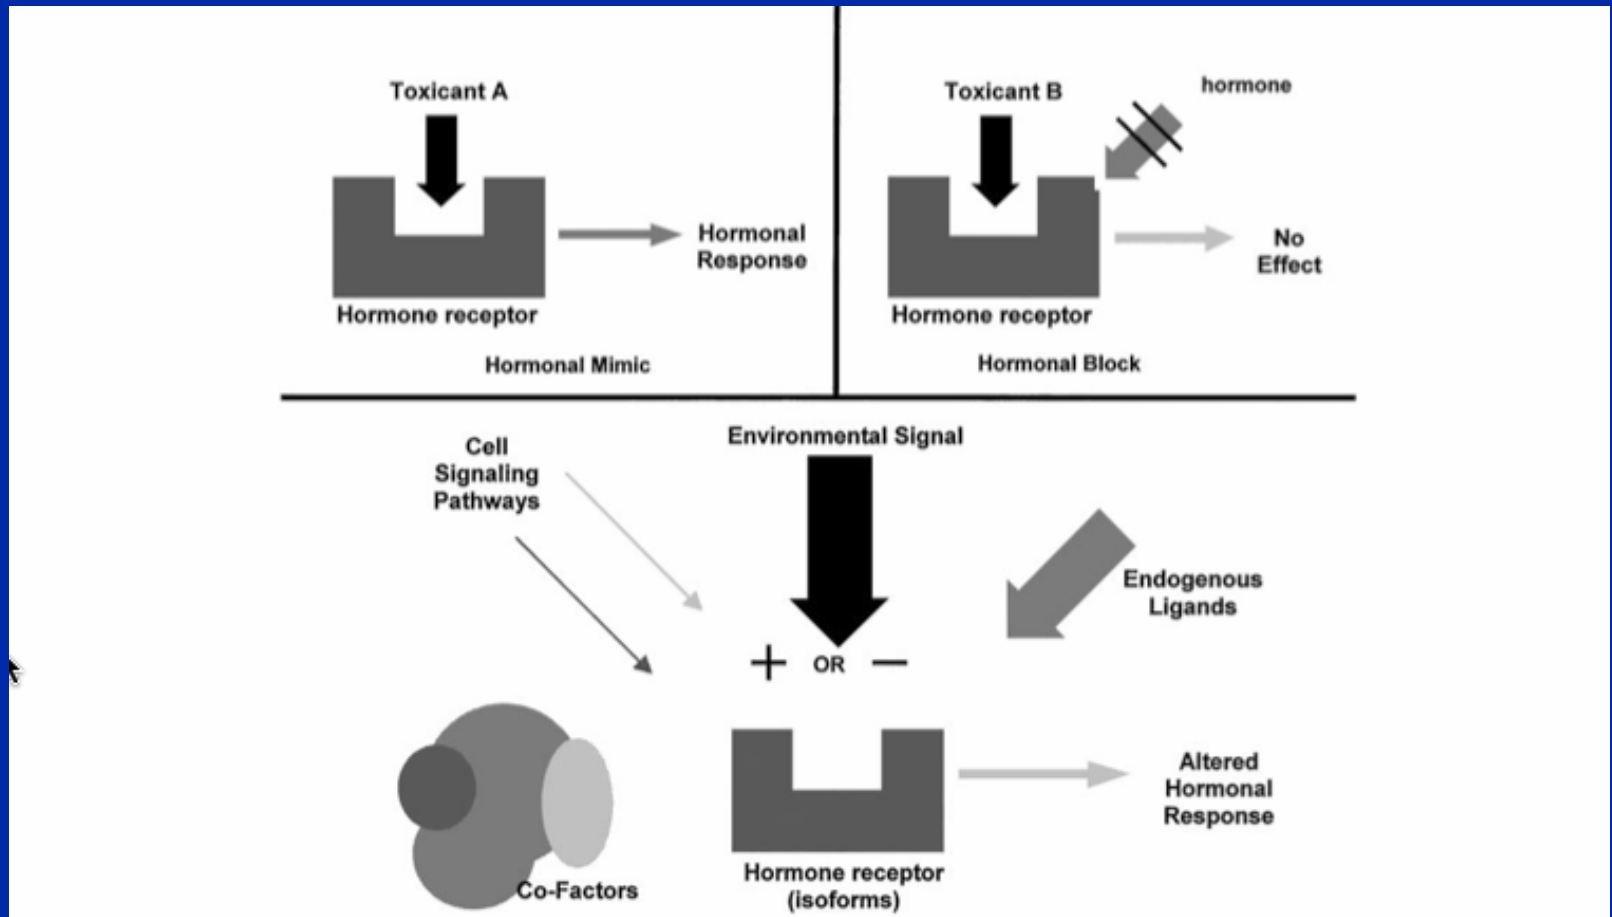

FIG. 6. Functional or receptor-based toxicology. The practice of using steroid hormone receptors to determine the hormonal or antihormonal activity of environmental chemicals is more than a decade old (49). The relatively simple concept presented then (*upper panels*), must now accommodate the advances in knowledge over the last 10 yr. These include the convergence of activating ligands and cellular signals on the ER (50), the multiple isoforms of the ER (51), contributions of coactivators and corepressors, and the gradation in response (50).

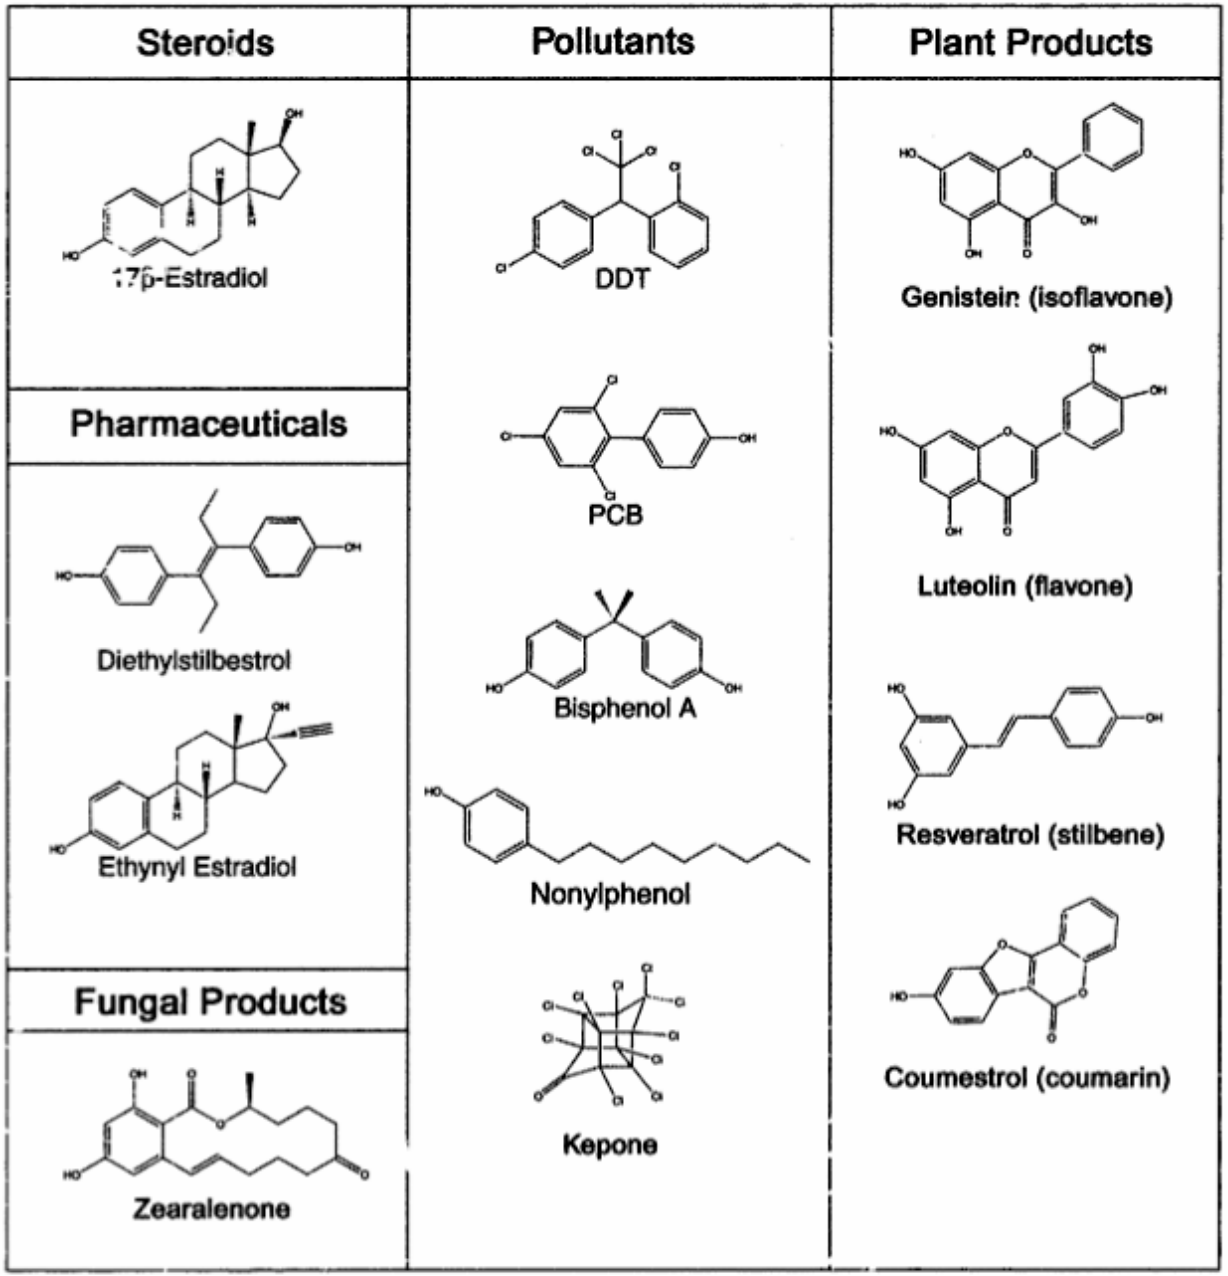

FIG. 5. Chemicals found in the environment reported to be estrogenic. This list is not comprehensive, but illustrates representative structures of estrogenic compounds from various sources. Information on these compounds is contained in the text.

TABLE 1. Environmental hormonal activities

Hormonal activity	Environmental	
	Hormone	Antihormone

[b] Androstenedione, the product of bacterial metabolism of stigmasterol; see Fig. 3.

[c] See representative structures in Fig. 2.

[d] Arsenic is reported to block the GR_I activation at the receptor binding level (23).

[e] PCB congeners elicit a thyroid hormone-like response, but no binding data for the thyroid hormone receptor is available (21). One study that evaluated binding of chlorinated hydrocarbons to the thyroid hormone receptor and thyroid binding proteins did not demonstrate specific receptor binding, while binding to transthyretin was of the same affinity as T_4 (22).

Cloning of a second ER...

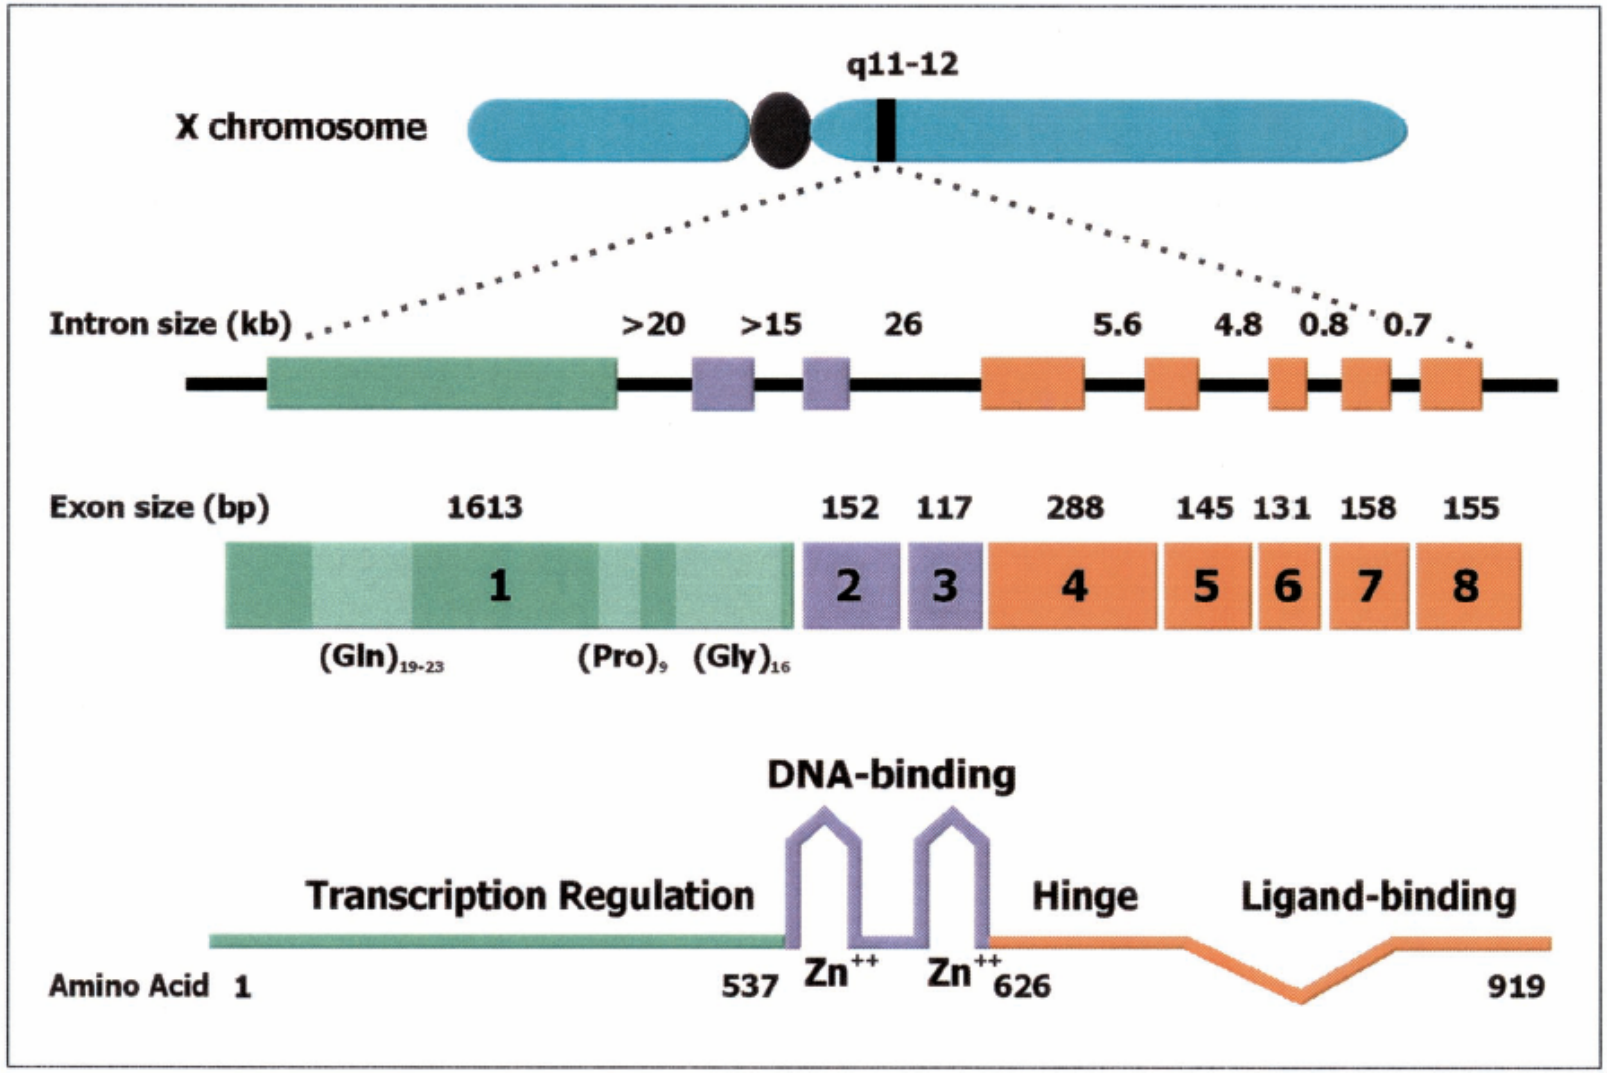

Fig 1. Genomic organization of the *AR* gene is shown. The genome spans more than 80 kb that includes the exonic organization shown in the second panel. Location of three codon repeat regions in the first exon that codes for the N-terminal domain is shown in the third panel. The diagram of the protein structure demonstrates how the exon organization translates into discrete functional regions of the receptor. Adapted from Quigley et al.[7]

Role of the different ER subtypes ?

Dorsal raphe	ERβ	Depression	ERβ agonist	[11]
Bone marrow	ERβ	Leukaemia	ERβ agonist	[20]

[a]A splice variant of ERβ.

Table 2. Differential actions of ERα and ERβ on different promoters and with different ligands[a]

Ligand	ER	Interaction site			
		ERE	AP-1[b]	Sp1	NF-κB promoter[c]
E2	ERα	↑	↑	↑ RARα1 promoter [24]; ↓ IGF-1 promoter [25]	↓
	ERβ	↑	NC	No change in RARα1 promoter; ↑ IGF-1 promoter	NC
Tamoxifen	ERα	↓	↓	↓ RARα1 promoter	↓
	ERβ	↓	↑	↑ RARα1 promoter	NC

[a]Abbreviations: AP-1, activating protein 1; E2, 17β-estradiol; ER, estrogen receptor; ERE, estrogen response element; IGF-1, insulin-like growth factor 1; NC, no change; NF-κB, nuclear factor κB; RAR, retinoic acid receptor; Sp1, GC-box binding protein; ↑, increased activity; ↓, decreased activity.

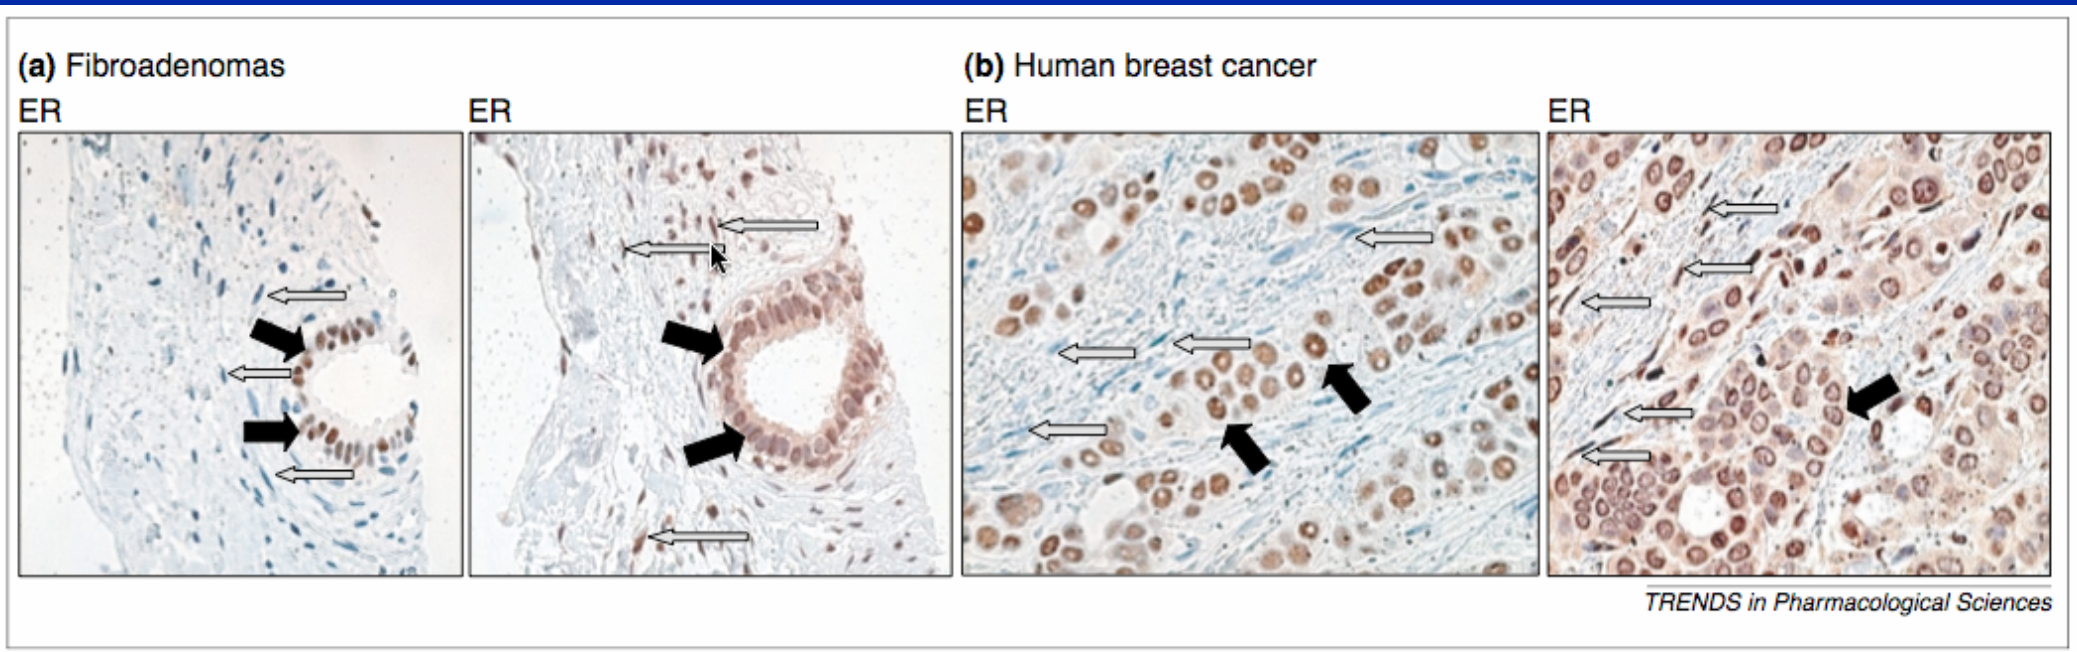

Fig. 1. **(a)** Estrogen receptor (ER) expression in fibroadenomas. ERα expression (brown) is exclusively epithelial (black arrows) with no stromal expression (grey arrows), whereas ERβ is expressed in both epithelial and stromal cells. **(b)** ER expression in human breast cancer. Note the intense staining for ERα in epithelial cells (black arrows) but no staining of the stroma (grey arrows). Intense ERβ (brown) staining is present in both epithelial and stromal cells. In both tissues, ERα expression was detected using a monolonal antibody (NovoCastra), whereas ERβ expression was detected using a polyclonal antibody (Upstate). All slides were lightly counterstained with hemotoxylin (blue). Reproduced, with permission, from the Society for Endocrinology [62].

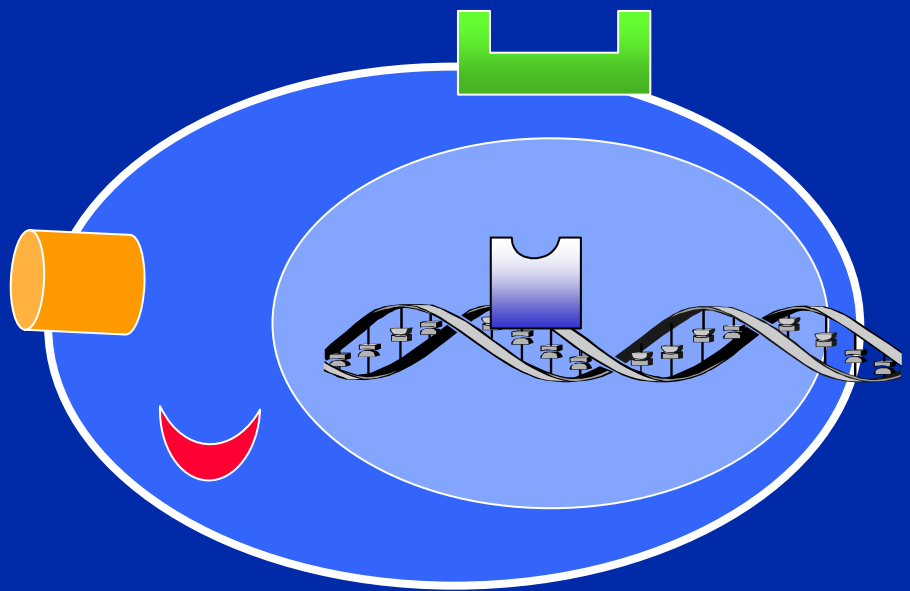

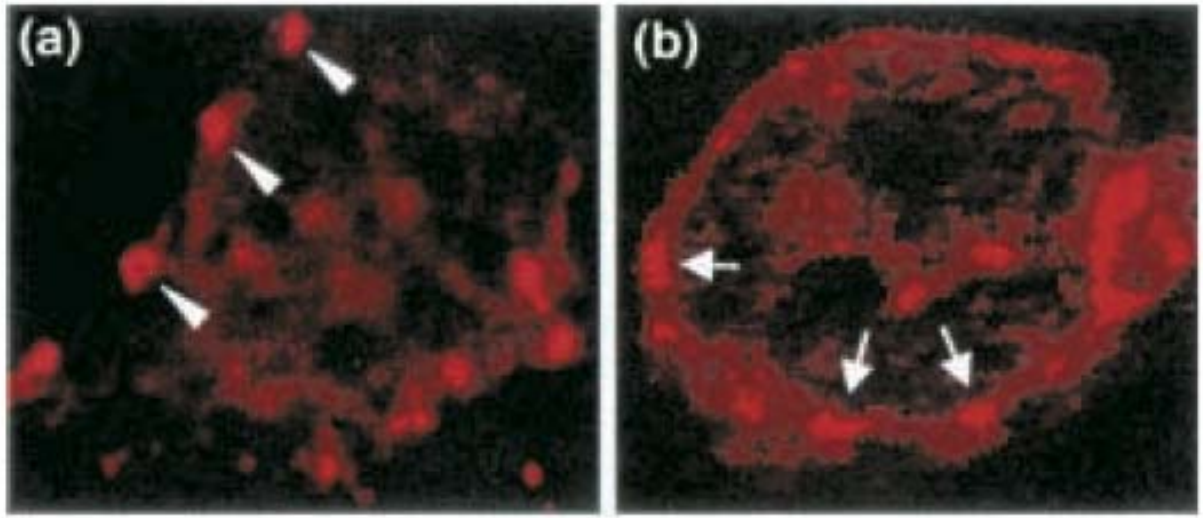

Fig. 1 Confocal analysis of ligand-labelling and immunocytochemical staining of cultured mouse midbrain neurones. **(a)** Living cells were exposed to 17-β-oestradiol coupled to hemisuccinate-BSA-FITC at a steroid concentration of approximately 1 nM for 5 min followed by a brief washing step and subsequent fixation. Note the presence of labelled clusters at the surface of the cell soma (arrowheads). Pre-incubation with unlabelled oestrogen completely prevented this staining. **(b)** Immunocytochemistry with an polyclonal antiserum specific for the nuclear oestrogen receptor-α. The arrows point at clusters of ER-α associated with the neuronal surface (magnification × 550).

Table 1. Potential Mechanisms by Which Selective Estrogen Receptor Modulators Produce Tissue-Selective Effects*

Differences in binding affinities to the estrogen receptor (22)
