# Strategies for Data Analysis: Cohort and Case-control Studies 

Post-Graduate Course, Training in Research in Sexual Health, 24 Feb 05

Isaac M. Malonza, MD, MPH<br>Department of Reproductive Health and Research<br>World Health Organization

## Objectives of the lecture

- Analyses tables of basic characteristics
- Review the design of Cohort studies
- Review the design of Case -control studies
- Calculating Absolute Risk, Relative Risks, Risk Difference, and Odds Ratios (ORs)
- 95\% confidence interval for Relative Risk and Odds Ratio
- Relationship between Odds Ratio and Relative Risk
- Interpretation of Relative Risk and Odds Ratio
- Data analysis from Matched Case-control Studies
- Confounding and Effect modification

## Analysis Table of Basic Characteristics

## Characteristics of participating women

| Characteristic | Rapid HIV test | ELISA test |
| :--- | :--- | :--- |
| Age in years(range) | $23(18-43)$ | $23(18-44)$ |

Marital status:

Single
Married
Other
Occupation
Housewife
Unemployed
Parity(range)

67(11\%)
548(88\%)
10(2\%)

62(10\%)
554(89\%)
4(1\%)
(Malonza et al, 2003)

368(59\%)
64(10\%)
1(0-9)

382(62\%)
46(8\%)
1(0-8)

## Design of Cohort Studies

- Investigator selects a group of individuals :
- exposed to the factor of interest (Exposed)
- not exposed to the factor of interest (Not exposed)
- Follows both groups to determine the incidence of disease (case) in the in two groups
- if exposure is associated with disease, we would expect that the incidence of disease among the exposed is greater than the incidence of disease among the non-exposed group
- since we identify new cases of disease as they occur in both groups, we can determine a temporal relationship between exposure and the development of disease
- Definition: A cohort is a group of individuals who share a common experience or condition

## Diagrammatic Representation of a Cohort Study

Exposed

No disease develops

Not Exposed

No disease develops

|  | Disease (yes) | Disease (no) | Totals | Incidence |
| :--- | :--- | :--- | :--- | :--- |
| Exposed | a | b | $\mathrm{a}+\mathrm{b}$ | $\mathrm{a} /(\mathrm{a}+\mathrm{b})$ |
| Not exposed | c | d | $\mathrm{c}+\mathrm{d}$ | $\mathrm{c} /(\mathrm{c}+\mathrm{d})$ |

$\cdot a /(a+b)$ equals the incidence of disease among the exposed ${ }^{\circ} \mathrm{c} /(\mathrm{c}+\mathrm{d})$ equals the incidence of disease in the non-exposed

## Objectives of Cohort Studies

- To estimate incidence, rate of occurrence and risk of disease
- To measure and compare the incidence of disease in one or more study cohorts
- To determine the aetiology of disease

## Risk and Absolute Risk

## Risk

- Definition: The proportion of individuals who develop a disease over a specified period of time

Risk $=\frac{\text { Number of people who develop disease }}{\text { Total population followed up }}$
e.g. 1000 people were observed for 3 years

950 did not develop disease
50 developed disease, Risk $=50 / 1000=0.05$
Absolute risk

- Definition: The incidence of a disease in a population
- Does not consider the incidence of disease in the unexposed, therefore cannot decide whether exposure is associated with disease

## Association between Exposure and Disease

- How do we determine that a certain exposure is associated with a disease of interest?
- Use data from a cohort or case-control study
- determine whether there is excess risk of the disease in persons who have been exposed
- Let us use a hypothetical investigation of a disease outbreak
- the suspect foods were identified and for each food, the incidence of disease was calculated for those who ate (exposed) and those who did not eat (not exposed) the type of food

## Food borne Disease Outbreak: Calculating Excess Risk

|  | $\mathrm{A}(\%$ sick $)$ | $\mathrm{B}(\%$ sick $)$ | risk | risk |
| :--- | :---: | :---: | :---: | :---: |
| Food | Ate | Not eaten | $\mathrm{A} / \mathrm{B}$ | $\mathrm{A}-\mathrm{B}$ |
| Fish | 60 | 30 | 2.00 | 30 |
| Rice | 78 | 67 | 1.16 | 11 |
| Meat | 72 | 50 | 1.44 | 22 |

methods of calculating excess risk:
1)calculate the ratio of attack rate in those who ate to those who did not eat (A/B)-risk ratio
2)subtract the risk in those who did not eat from those who ate (A-B)-risk difference

## Excess Risk

- To determine whether a certain exposure (specific food) is associated with a certain disease (diarrhea), we need to determine whether there is excess risk
- Excess risk=comparison of risk of disease in exposed population to risk of disease in nonexposed population:
- Ratio of the risks: Disease risk in exposed Disease risk in non-exposed
- Difference in the risks (or of the incidence rates):
(disease risk in exposed-disease risk in non-exposed)

## Risk Ratio and Risk Difference

- Question: does the method we use to calculate Excess Risk make any difference?
- Consider a hypothetical example of two communities $X$ and $Y$ :

|  | $X$ | $Y$ |  |
| :--- | :--- | :--- | :--- |
| Incidence (\%) |  |  |  |
| in exposed | 40 | 90 |  |
| in non-exposed | 10 | 60 |  |
| Difference in risks | 30 | 30 |  |
| Risk ratio | 4.0 | 1.5 |  |

## Relative Risk

- Cohort and case-control studies are designed to determine whether there is an association between exposure and disease
- if an association exists, we would like to know how strong it is
- For cohort studies, the question to ask is:

What is the ratio of risks of disease in exposed persons to the risk of disease in non-exposed individuals?

- This ratio is called the Relative Risk:

Relative risk = Risk in exposed
Risk in non-exposed

## Calculating the Relative Risk

Relative risk=incidence in exposed
incidence in non-exposed $\quad \frac{a / a+b}{c / c+d}$

- Example: Smoking versus CHD

|  |  | Did not <br> Developed <br> develop |  | incidence <br> per 1,000 <br> per year |
| :--- | :--- | :--- | :--- | :--- |
|  | CHD | CHD | Totals_ | 27.3 <br> Smokers |
| Non smokers | 86 | 2,918 | 3,000 | 17.2 |

Incidence among exposed= 82/3000=27.3 per 1000
Incidence among non-exposed= 86/5000=17.2 per 1000
Relative risk= 27.3/17.2=1.58

## Incidence Density Relative Risk

- In most studies, not all enrolled persons are followed up for the entire duration of the study
- the time each person (person-time) contributes to the study is therefore taken into consideration
- person-time is therefore used as the denominator instead of number of persons enrolled
- this type of relative risk is called the incidence density relative risk (IDR)

## Analysis Table for IDR

|  | Exposed | Unexposed | Total |
| :--- | :---: | :---: | :---: |
| Cases | a | b | $\mathrm{m}_{1}$ |
| Person-time | $\mathrm{n}_{1}$ | $\mathrm{n}_{0}$ | t |

IDR =

$$
\frac{\mathrm{a} / \mathrm{n}_{1}}{\mathrm{~b} / \mathrm{n}_{0}}
$$

a=number of cases among the exposed, $\mathrm{b}=$ the number among the unexposed, $n_{1}=$ person-time among the exposed, and $\mathrm{n}_{0}=$ person-time among the unexposed,

## Confidence Interval for Relative Risk

- Confidence interval $=\mathrm{RR}(1 \pm \mathrm{z} / \mathrm{x})$ where $z$ is the normal variate (1.96), and $x^{2}=\frac{(t-1)^{*}\left[\left(a^{*} d\right)-\left(b^{*} c\right)\right]^{2}}{n_{1}{ }^{*} n_{2}{ }^{*} m_{1}{ }^{*} m_{0}}$
- Confidence interval that include 1 implies no association between exposure and disease

## Interpreting the Relative Risk

- If RR=1 risk in exposed equals risk in nonexposed (no effect/association)
- If RR>1 risk in exposed greater than risk in nonexposed (positive association, possibly causal)
- If $R R<1$ risk in exposed less than risk in nonexposed (negative association, possibly protective)
- If confidence interval includes 1 , then the RR is not significant (no association)

## Design of Case-control Studies

- Identify a group of individuals with the disease (cases)
- Select a group of individuals without the disease (controls)
- Determine the proportion of cases who were exposed and those that were not exposed
- Then do the same for control (exposed versus nonexposed)

## Diagrammatic Representation of a Case-control Study

Non-exposed

## Summarising data from case-control studies using a 2 by 2 table

|  | Cases | Controls | Total |
| :--- | :---: | :---: | :---: |
| Exposed | A | B | $(\mathrm{A}+\mathrm{B}) \mathrm{M}_{1}=$ |
| Non- <br> exposed | C | D | $(\mathrm{C}+\mathrm{D}) \mathrm{M}_{2}=$ |
| Total | $\mathrm{A}+\mathrm{C}=\mathrm{N}_{1}$ | $\mathrm{~B}+\mathrm{D}=\mathrm{N}_{2}$ | $\mathrm{M}_{1+} \mathrm{M}_{2}=\mathrm{T}$ |

> Proportion of cases exposed $=A /(A+C)$ Proportion of controls exposed $=B /(B+D)$

If disease is associated with exposure, we expect the proportion of cases who are exposed to be higher than the proportion of controls who are exposed, i.e
$A /(A+C)$ greater than $B /(B+D)$

Hypothetical example: coronary heart disease (CHD) versus history of smoking

## CHD

| Smoking | 56 | 88 |
| :--- | :--- | :--- |
| No smoking | 44 | 112 |
| Total | $\mathbf{1 0 0}$ | $\mathbf{2 0 0}$ |
| Proportions (exposed) | $56 \%$ | $44 \%$ |

This implies that history of smoking may be associated with development of CHD.

## Odds Ratio (1)

## Cases Controls A C <br> B D

Exposed Non-exposed

$$
A+C \quad B+D
$$

- A divided by $(\mathrm{A}+\mathrm{C})$ is the probability that a case was exposed
- C divided by $(\mathrm{A}+\mathrm{C})$ is the probability that a case was not exposed
- $\mathrm{A} /(\mathrm{A}+\mathrm{C})$ divided by $\mathrm{C} /(\mathrm{A}+\mathrm{C})$ is a ratio of two probabilities which is called odds
- Odds of a case being exposed $=\mathrm{A} /(\mathrm{A}+\mathrm{C})$ divided by $\mathrm{C} /(\mathrm{A}+\mathrm{C})$ = A/C

## Odds Ratio (2)

- the odds of an event is defined as the ratio of the number of ways the event can occur to the number of ways the event cannot occur, i.e.

$$
\text { Odds }=\quad \frac{\text { No. of ways event can occur }}{\text { No. of ways event cannot occur }}
$$

- $\mathrm{A} / \mathrm{C}$ is the odds that a case was exposed
- B/D is the odds that a control was exposed

$$
\text { Odds ratio }(\mathrm{OR})=\mathrm{A} / \mathrm{C} \text { divided by } \mathrm{B} / \mathrm{D}=\mathrm{AD} / \mathrm{BC}
$$

Definition: OR in case-control studies is defined as the ratio of the odds that the cases were exposed to the odds that the controls were exposed.

## Odds Ratio from Cohort Studies

- A divided by B is the odds that the exposed will develop disease
- C divided by D is the odds that the non- exposed will develop disease
- OR=A/B divided by C/D=AD/BC
- Therefore, AD/BC represents the odds ratio in both case-control and cohort studies,
- OR in a cohort studies is defined as the ratio of the odds that the exposed persons will develop disease to the odds that the non-exposed will develop the disease.

## Recapitulate

- Note that AD/BC has a different meaning depending on whether its from a case-control or cohort study
- OR in case-control studies is defined as the ratio of the odds that the cases were exposed to the odds that the controls were exposed

OR in a cohort studies is defined as the ratio of the odds that the exposed persons will develop disease to the odds that the non-exposed will develop the disease

## Interpreting the Odds Ratio

- If $O R=1$, the exposure is not related to the disease
(no association)
- If OR>1, the exposure is positively related to the disease (possible causal)

If $\mathrm{OR}<1$, the exposure is negatively related to the disease (possible protective)

# Calculating OR from Case-control Studies 

## CHD Controls

Smoking
No smoking

56
44
112
OR= $(56 \mathrm{X} \mathrm{112}) /(88 \mathrm{X} 44)=6272 / 3872=1.6$
Indicating that smoking increases the odds of developing CHD

## Suppose we rearrange the order of columns

## CHD

| No Smoking | 44 | 112 |
| :--- | :---: | :---: |
| Smoking | 56 | 88 |
| OR $=(44 \times 88) /(112 ~ X ~ 56) ~$ | $=3872 / 6272=0.6$ |  | Indicating that non-smoking reduces the odds of developing CHD

## CHID Controls <br> Smoking <br> No smoking <br> 112 <br> 88

## Controls

## 112

88

## Odds Ratio from Matched Pairs Case - control study

- Controls may be matched to each case according to a certain factor, e.g. age, sex, race
- Analysis is done for case-controls pairs, not by individual subjects
- What types of combinations are possible?
- Assume that exposure is dichotomous (either exposed or not exposed)
- Possibilities:

1. Both cases and controls exposed
2. Neither case nor control was exposed
3. Case exposed, but control not exposed
4. Control exposed, but case not exposed

1 and 2 are called concordant pairs
3 and 4 are discordant pairs

## Summarize the Data into a $2 \times 2$ Table

## Controls

Cases Exposed Not exposed

Exposed Not exposed
a
C
b
d

Note: a, b, c, d, represent pairs

- concordant pairs (a and d) had the same exposure experience, therefore they cannot tell anything about the relationship between exposure and outcome
- calculation of OR is based on the discordant pairs, b and c
- OR=b/c
- Definition: OR in a matched case-control study is defined as the ratio of the number of pairs a case was exposed and the control was not to the number of ways the control was exposed and the case was not
-OR = \# Pairs (case exposed and control not exposed)
\# Pairs (control exposed and case not exposed)

# Hypothetical Example: Matched Case-control Study 

| Cases | Controls |
| :---: | :---: |
| E | N |
| E | E |
| N | N |
| E | N |
| N | E |
| N | N |

Controls
Exposed Not exposed
1
2
Cases Exposed
Not
exposed
1
2
$\mathrm{OR}=2 / 1=2.0$

## Matched Case-control Study with R Number of Controls per Case

| cases | 0 | 1 | 2 | $\ldots$ | $\mathbf{R}$ |
| :--- | :---: | :---: | :---: | :---: | :---: |
| exposed | $\mathrm{F}_{10}$ | $\mathrm{~F}_{11}$ | $\mathrm{~F}_{12}$ | $\ldots$ | $\mathrm{~F}_{1 \mathrm{R}}$ |
| Not <br> exposed | $\mathrm{F}_{00}$ | $\mathrm{~F}_{01}$ | $\mathrm{~F}_{02}$ | $\ldots$ | $\mathrm{~F}_{0 \mathrm{R}}$ |

$\mathrm{F}_{10}=\mathrm{no}$. of times the case is exposed and none of the controls are exposed
$\mathrm{F}_{11}=\mathrm{no}$. of times the case is exposed and one of the controls are exposed
$\mathrm{M}=$ total no. of exposed subjects in a matched set $(0 \leq m \leq$ $\mathrm{R}+1$ )
$\mathrm{OR}_{\mathrm{MH}}=$
$\left\{R F_{1,0}+(R-1) F_{1,1}+(R-2) F_{1,2}+\ldots+F_{1, R-1}\right\} /\left\{F_{0,1}+2 F_{0,2}+\right.$ $\left.\mathbf{3 F}_{0,3}+\ldots+\mathrm{RF}_{0, \mathrm{R}}\right\}$

## Example:

Previous history of induced abortion among women with ectopic pregnancy and matched controls

|  | controls |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| cases | 0 | 1 | 2 | 3 | 4 |  |
| Exposed | 3 | 5 | 3 | 0 | 1 |  |
| Not <br> exposed | 5 | 1 | 0 | 0 | 0 |  |

$$
\begin{aligned}
& \text { OR }_{M H}=\{4 \times 3+3 \times 5+2 \times 3 \\
& +1 \times 0\} /\{1+2 \times 0+3 \times 0+4 \times 0\}=33 / 1=33
\end{aligned}
$$

## Calculating OR from data with continuos exposure

Daily cigarette consumption
$\begin{array}{lllll}<5 & 5-14 & 15-24 & 25-49 & 50+\end{array}$
$\begin{array}{llllll}\text { Lung cancer } 26 & 208 & 196 & 174 & 45\end{array}$

| smoking | Lung cancer | controls |
| :--- | :--- | :--- |
| $5-14$ | 208 | 242 |
| $<5$ | 26 | 65 |

$\mathrm{OR}=2.1$

- We can therefore calculate OR for each smoking categories compared to <5 group
- We get a list of OR as shown in the next slide

## Daily Cigarette Consumption

|  | $\leq 5$ | $5-14$ | $15-24$ | $25-49$ | $50+$ |
| :--- | :--- | :--- | :--- | :--- | :--- |
| Lung cancer | 26 | 208 | 196 | 174 | 45 |
| Controls | 65 | 242 | 201 | 118 | 23 |
| OR | 1 | 2.1 | 2.4 | 3.7 | 4.9 |

Smoking more that 5 cigarettes per day increases the odds of developing lung cancer

Suppose we had multiple outcomes, e.g. different types of cancer, then you have to calculate OR for each type of cancer.

## Calculating the 95\% Confidence Interval (CI) for Odds Ratios

- Epidemiologic studies usually involve only a sample of the entire population
- However, the main interest is to use the sample to make conclusions about the entire population
- Question: how does the OR from the sample differ from that for the entire population?
- We would like to be $95 \%$ confident that the population OR lies within a certain range
- This range is referred to as the confidence interval (CI)

CI for the OR (Mantel and Haenszel, 1959, Miettinen, 1976): CI=OR ${ }^{(1 \pm Z / x)}$
Where $\mathbf{Z}$ is the normal variate and $\mathbf{x}=$ square root of $(\mathbf{T}-1) \mathbf{x}(\mathbf{A D}-\mathrm{BC})^{2}$

$$
\mathbf{N}_{0} \times \mathbf{N}_{1} \times \mathbf{M}_{1} \times \mathbf{M}_{0}
$$

# Estimating the CI from "The Cancer and Steroid hormone study, 1987" 

|  | Ovarian cancer | Controls | Total |
| :--- | :---: | :---: | :---: |
| OC use | 250 | 2,696 | $\mathbf{2 , 9 4 6}$ |
| NO OC | 242 | 1,532 | $\mathbf{1 , 7 7 4}$ |
| Total | $\mathbf{4 9 2}$ | $\mathbf{4 , 2 2 8}$ | $\mathbf{4 , 7 2 0}$ |

Step 1: calculate the $X^{2}=4,719 \times(250 \times 1,532-242 \times 2.696)=31.51, \quad x=5.61$ $2,696 \times 1,532 \times 250 \times 242$

Step 2: Lower limit: OR ${ }^{(1-Z / x)}$, where Z is $1.96,=0.5$
Step 3: Upper limit, OR ${ }^{(\mathbf{1}+\mathbf{Z} / \mathbf{x})},=0.7$

## Relationship between OR and RR

- Relative risk = incidence in exposed/incidence in non-exposed -cannot measure RR directly from a case-control study
- OR is a good estimate of RR when:
1)the disease or event is rare

2) cases are representative of the all people with the disease with regard to exposure
3) controls are representative of all people without disease in the population
-Example:

| exposed | 200 | 9800 |
| :--- | :--- | :--- |
| non exposed | 100 | 9900 |

$R R=(200 / 10,000) /(100 / 10,000)=2.0$
OR=2.02

## Confounding

- Definition:
- factor is associated with both exposure and outcome
- but factor not a result of exposure
- hides the true relationship between exposure and outcome
- Controlling for confounding
- Study design stage: Matching (individual or group)
- Data analysis stage: Stratification and Adjustment

## Controlling for Confounding (1)

Example of Education, Cervical cancer and OC use:
OC non users

| Education | cancer | controls |
| :--- | :---: | :---: |
| High | 3 | 33 |
| Low | 47 | 16 |
| Total | 50 | 49 |
| \%high | $6 \%$ | $67 \%$ |

All women

| Education | cancer | controls |
| :--- | :---: | :---: | :---: |
| High | 8 | 75 |
| Low | 92 | 25 |
| Total | 100 | 100 |
| \%high | $8 \%$ | $75 \%$ |

Conclusion: women with cervical cancer were more likely than controls to have 'low' level of education

## Controlling for Confounding (2)

## High education

| OC | cases | controls | OR |
| :--- | :---: | :---: | :---: |
| + | 5 | 42 |  |
| - | 3 | 33 | 1.31 |

Low education

| OC | cases | controls | OR |
| :--- | :---: | :---: | :---: |
| + | 45 | 9 |  |
| - | 47 | 16 | 1.70 |

All volunteers

| OC | cases | controls | OR |
| :---: | :---: | :---: | :---: |
| + | 50 | 51 |  |
| - | 50 | 49 | 0.96 |

Standardized OR $=(5 \times 33) / 83+(45 \times 16) / 117=1.59$ $(42 \times 3) / 83+(9 \times 47) / 117$

## Effect Modification

- Definition:
- present when the relationship between exposure and outcome is different for various subgroups in the study population
- detected by stratifying the analysis by each stratum and comparing the RRs for the strata

| Maternal age (<25yrs) | Anemia | No Anemia |  |
| :--- | :--- | :--- | :--- |
| Low birthweight | 13 | 4 |  |
| Normal birthweight | 18 | $17 \quad$ IR=2.2 |  |
|  |  |  |  |
| Maternal age (>25yrs) | Anemia | No Anemia |  |
| Low birthweight | 5 | 4 |  |
| Normal birthweight | 37 | $31 \quad$ IR=1.0 |  |

(To rule out of confounding: Overall IR=1.7, Adjusted =1.6)
