## $\boldsymbol{s}$

Reproductive Health and Research

## Prevalence of exposure in cases and controls

In case-control studies we can calculate:

- Prevalence of exposure in cases and in controls $a /(a+c)$ and $b /(b+d)$

We cannot calculate prevalence of disease, or risk for exposed and for non-exposed

## We cannot calculate the relative risk (RR)

## Odds of exposure

In case-control studies we can calculate:

- The odds ratio to measure association between disease and exposure:

The odds of being exposed for a case is a/c The odds of being exposed for a control is $\mathrm{b} / \mathrm{d}$

The odds ratio of exposure for cases vs controls is

$$
\mathrm{OR}_{\mathrm{Exp}}=(\mathrm{a} / \mathrm{c}) /(\mathrm{b} / \mathrm{d})=(\mathrm{a} \times \mathrm{d}) /(\mathrm{b} \times \mathrm{c})
$$

## Odds ratio (OR)

## Disease No disease

Exposed

Non-exposed

Odds $_{\text {Exp }}$
$a / c \quad b / d$

## $O_{\text {Exp }}=a / c / b / d=a d / b c$

## Odds ratio (OR)

## Disease No disease

ORExp $=(\mathrm{a} / \mathrm{c}) /(\mathrm{b} / \mathrm{d})=(\mathrm{a} \times \mathrm{d}) /(\mathrm{b} \times \mathrm{c})=(\mathrm{a} / \mathrm{b}) /(\mathrm{c} / \mathrm{d})=$ ORDis

## Interpretation of the odds ratio

- If exposure and disease are not associated, $\mathrm{OR}=1$
- If exposure and disease are positively associated, OR>1
- If exposure and disease are negatively associated, $\mathrm{OR}<1$

The OR is a good estimation of the RR if the disease is rare

## Confidence intervals for the OR

There are several methods:
-Woolf's method: approximate
-Cornfield method: iterative
-Test-based method
-Logistic regression

We usually work in the log scale, In OR Woolf's method:
$S E \ln O R=\sqrt{ }(1 / a+1 / b+1 / c+1 / d)$
95\% CI for $\ln$ OR: $\ln$ OR $\pm z_{0.025} x \sqrt{ }(1 / a+1 / b+1 / c+1 / d)$
95\% CI for the OR: OR $x \exp \left[ \pm z_{0.025} \times \sqrt{ }(1 / a+1 / b+1 / c+1 / d)\right]$

## Strategy for data analysis for case-control studies

- Describe study profile: number of cases and controls, identified and analyzed
- Baseline characteristics of cases and controls
- Crude ORs for different categories of use and risk factors
- ORs for different categories of use and risk factors, adjusting for confounders

## Example: Oral contraceptives and breast cancer in young women

Lancet 1985; 326:970-972
Study aim was to investigate relation between use of oral contraceptives (OCs) by young women and their risk of breast cancer.
Cases: women 20-44 years at initial diagnosis of breast cancer, between Dec 11980 and Dec 31 1982, resident in 8 regions of the US, identified from population-based cancer registries.
Controls: women 20-44 years selected during same 25 months as the cases were diagnosed, residents of the 8 regions, selected randomly by telephone calls to households.

## Oral contraceptives and breast cancer Study profile: cases

6.4\% refused to participate
3.7\% died or were too ill
8.7\% miscellaneous reasons

## Oral contraceptives and breast cancer Study profile: controls

11.2\% refused to participate 2.2\% moved out
3.0\% miscellaneous reasons

## Oral contraceptives and breast cancer Baseline characteristics of cases and controls

1.6

## Conclusions about baseline analysis

- Cases were older at diagnosis than controls were at selection
- Larger proportion of cases had family history of breast cancer
- Slightly larger proportion of cases had late age at first pregnancy
- Larger proportion of cases had benign breast disease surgery

## Oral contraceptives and breast cancer Results: crude ORs

|  | Cases | Controls |
| :--- | :---: | :---: |
| Exposed | 1701 | 1662 |
| Non-exposed | 387 | 403 |
| All | OR=1.07 |  |
|  | 2088 | 2065 |

## $\boldsymbol{\Re}$

Reproductive Health and Research

The odds of being exposed for a case is $1701 / 387=4.4$
The odds of being exposed for a control is $1662 / 403=4.1$

The odds ratio of exposed vs non-exposed is OR $=(1701 / 387) /(1662 / 403)=$
$=(1701 \times 403) /(1662 \times 387)=1.07$

95\% CI: 0.91 to 1.25

## Stratification and confounding variables?

- Age: main purpose was stratifying by age

## Oral contraceptives and breast cancer Results: crude ORs

Age at
diagnosis

| or <br> selection | N | \% ever <br> users |  |  |  |  |
| :--- | ---: | :--- | :--- | :--- | :--- | :---: |
|  |  |  |  | \% ever <br> users |  | OR |
| $20-24$ | 15 | 100.0 |  | 106 | 69.8 | - |
| $25-29$ | 126 | 86.5 |  | 169 | 87.6 | 0.91 |
| $30-34$ | 382 | 89.3 |  | 429 | 88.1 | 1.13 |
| $35-39$ | 700 | 86.4 |  | 590 | 85.1 | 1.11 |
| $40-44$ | 865 | 73.0 |  | 771 | 72.6 | 1.02 |
| Total | 2088 | 81.5 |  | 2065 | 80.5 | 1.07 |

## Oral contraceptives and breast cancer results: adjusting

We need to adjust for factors associated with the risk of breast cancer or with the likelihood of diagnosis:

- Family history of breast cancer
- Age at first term pregnancy
- History of surgery for benign breast disease
- Frequency of breast examination

Techniques to adjust ORs:

- Logistic regression
- Mantel-Haenszel

## Oral contraceptives and breast cancer Results: adjusted ORs

| Age at diagnosis or selection | Cases(\%) |  | Controls(\%) |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  | N | \% ever users | N | \% ever users | $\begin{array}{r} \text { OR(95\% CI) } \\ \text { (adjusted) } \end{array}$ |
|  |  |  |  |  |  |
|  |  |  |  |  |  |
| 20-24 | 15 | 100.0 | 106 | 69.8 | - |
| 25-29 | 126 | 86.5 | 169 | 87.6 | 1.0 (0.5-2.1) |
| 30-34 | 382 | 89.3 | 429 | 88.1 | 1.2 (0.7-1.8) |
| 35-39 | 700 | 86.4 | 590 | 85.1 | 1.1 (0.8-1.6) |
| 40-44 | 865 | 73.0 | 771 | 72.6 | 1.1 (0.9-1.4) |
| Total | 2088 | 81.5 | 2065 | 80.5 |  |

## Oral contraceptives and breast cancer Results: adjusted ORs

1.3 (1.0-1.7)
1.1 (0.9-1.5)
1.2 (0.9-1.6)

1897

## Oral contraceptives and breast cancer Conclusions

There was no significant increase or decrease in the risk of breast cancer for OC users according to

- Age at diagnosis
- Age at first use
- Duration of use
- Use before first term pregnancy

Use of OCs by young women in the US has no effect on the risk of breast cancer before 45 years of age
